ABSTRACT
The asymptotically fastest known divide-and-conquer methods for inverting dense structured matrices are essentially variations or extensions of the Morf/Bitmead-Anderson algorithm. Most of them must deal with the growth in length of intermediate generators, and this is done by incorporating various generator compression techniques into the algorithms. One exception is an algorithm by Cardinal, which in the particular case of Cauchy-like matrices avoids such growth by focusing on well-specified, already compressed generators of the inverse. In this paper, we extend Cardinal’s method to a broader class of structured matrices including those of Vandermonde, Hankel, and Toeplitz types. Besides, some first experimental results illustrate the practical interest of the approach.

Structured linear algebra, matrix inversion

1. INTRODUCTION
Since [10], a classical way of exploiting the structure of dense matrices is via the displacement rank approach: typically, $n \times n$ matrices are represented by pairs $(G, H)$ of $n \times \alpha$ matrices such that $L(A) = GH^T$ for some linear operator $L$ called a displacement. Classical choices for $L$ are Stein’s displacement $\Delta[M, N] : A \mapsto A - MAN$ and Sylvester’s displacement $\nabla[M, N] : A \mapsto MA - AN$. With respect to a given displacement, $(G, H)$ is called a generator of length $\alpha$ for $A$, and $A$ is considered to be structured when $\alpha$ is “small” (in a sense that depends on the context) compared to $n$. According to the unified treatment [19], many of the structures encountered in practice are covered by the following operator matrices: for a field $\mathbb{K}$ and a positive integer $n$, let

$$M, N \in \{D(x), Z_{n,\varphi}, Z_{n,\psi}^T\}, \quad x \in \mathbb{K}^n, \quad \varphi, \psi \in \mathbb{K}, \quad (1)$$

with $D(x)$ the diagonal matrix whose entry $(i, i)$ is the $i$th coefficient $x_i$ of vector $x$, and $Z_{n,\varphi}$ the $n \times n$ unit $\varphi$-circulant matrix having a $\varphi$ in position $(1, n)$, ones in positions $(i + 1, i)$, and zeros everywhere else.

When a structured matrix $A \in \mathbb{K}^{n \times n}$ is invertible, its inverse $A^{-1}$ is known to be structured too, and some asymptotically fast algorithms are available for computing length-\(\alpha\) generators for $A^{-1}$ and linear system solutions, whose costs in terms of operations in $\mathbb{K}$ are in $O(\alpha^2 n)$ (see [19] and the references therein) and, since more recently, in $O(\alpha^{n-1})$ (see [2, 3]). (Here and hereafter the $O$ notation hides all logarithmic factors.) Such algorithms are essentially variations or extensions of the Morf/Bitmead-Anderson (MBA) divide-and-conquer approach [13, 1]. In practice, they apply to important types of structures like those of (1). However, most of these algorithms must deal with the growth in length of intermediate generators, and this is done by recursively using a generator compression stage which, given matrices $G, H \in \mathbb{K}_a^{\alpha \times \beta}$ such that $G^H H$ has rank $\alpha \leq \beta$, computes matrices $G_\alpha, H_\beta$ that satisfy $G_\alpha H_\beta^T = G^H H$ but now have exactly $\alpha$ columns; see [17, 15, 16, 11, 12] and [19, §4.6].

One exception is a variant of MBA due to Cardinal [4, 5]: assuming Sylvester’s displacement equation

$$\nabla[M, N](A) = GH^T \quad (2)$$

and in the particular case where both $M$ and $N$ are diagonal (Cauchy-like structure), Cardinal’s algorithm completely avoids generator compression by directly computing

$$Y = -A^{-1}G, \quad Z = A^{-T}H. \quad (3)$$

As already noted in [9]—and this is readily verified by pre- and postmultiplying (2) with the inverse of $A$—, the matrix pair $(Y, Z)$ is a $\nabla[N, M]$-generator of length $\alpha$ for $A^{-1}$. Due to its very special form, we shall call it a specified generator for the inverse of $A$.

The goal of this paper is to extend Cardinal’s algorithm beyond the Cauchy-like structure and to show that, in MBA and for Sylvester’s displacement, generator compression can be systematically avoided by targeting a specified generator for the inverse, rather than just an arbitrary one of length $\alpha$. More precisely, our three main contributions can be summarized as follows:

First, we propose a recursive formula that allows to factor a specified generator of the inverse for $A$ in terms of specified generators for the inverse of its upper-left block $A_{11}$ and for the inverse of the Schur complement of $A_{11}$ in $A$.

Second, we show how to reduce the computation of specified inverse generators for the structures defined in (1) to the computation of specified inverse generators for the three basic cases below:

$$\begin{align*}
(M, N) &\in \left\{ (D(x), D(y)), (D(x), Z_{n,0}^T, 0), (Z_{n,0}^T, Z_{n,0}^T) \right\}. 
\end{align*}$$

For each of those three structures, which are of the Cauchy-like, Vandermonde-like, and Hankel-like types, respectively, we further give and analyze explicit algorithms for computing a specified generator of the inverse. These algorithms are compression-free and thus, in that sense, simpler to analyze and implement than traditional MBA variants. Moreover, although removing generator compression does not affect the overall asymptotic costs, it yields smaller dominant terms.

Third, we report on a first set of experiments done with our C++ implementation of MBA and of several of the new compression-free algorithms. For the Cauchy-like structure, for example, the speed-ups compared to MBA are by a factor from 4.6 to 6.7. This suggests that our extension of Cardinal’s compression-free approach may yield algorithms that are not only simpler but also significantly faster in practice.

**Outline of the paper.** After some notation and preliminaries in §2, some properties of specified generators are studied in §3. Then §4 gives a compression-free algorithm for the case where $M$ and $N^T$ are lower triangular. The algorithm is specialized to the Cauchy-like and Vandermonde-like structures in §4.1 and §4.2, and then extended in §4.3 to the irregular Hankel-like case $(M, N) = (Z_{n,0}, Z_{n,0}^T)$. Experiments are reported in §5 and we conclude in §6.

## 2. NOTATION AND PRELIMINARIES

Here and hereafter, $I_n$ is the identity matrix of order $n$, $e_{n,i}$ is the $i$th unit vector of $K^n$, and $J_n$ is the reflexion matrix of order $n$, whose $(i, j)$ entry is 1 if $i + j = n + 1$, and 0 otherwise. For $A \in K^{n \times n}$, $a_{i,j}$ denotes its $(i,j)$ entry and $a_j$ its $j$th column. Also, for $\alpha \leq m$, we write $A^{\alpha \times \alpha}$ for the matrix $[a_1, \ldots, a_\alpha] \in K^{n \times \alpha}$.

Given positive integers $n_1$ and $n_2$ such that $n_1 + n_2 = n$, we will often partition $A, G, H, M, N$ into $n_1 \times n_1$ blocks as

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}, \quad G = \begin{bmatrix} G_{11} \\ G_{21} \end{bmatrix}, \quad H = \begin{bmatrix} H_{11} \\ H_{21} \end{bmatrix}. \quad (5)$$

$$M = \begin{bmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{bmatrix}, \quad N = \begin{bmatrix} N_{11} & N_{12} \\ N_{21} & N_{22} \end{bmatrix}. \quad (6)$$

We shall write $\mu$ and $\nu$ for the rank of, respectively, $M_{12}$ and $N_{21}$. Consequently, those two matrices can be written

$$M_{12} = U_1 V_1^T, \quad N_{21} = U_2 V_1^T \quad (7)$$

for some full column rank matrices $U_1 \in K^{n_1 \times \nu}$, $V_1 \in K^{n_2 \times \nu}$, and $V_1 \in K^{n_2 \times \nu}$. The Schur complement of $A_{11}$ in $A$ is written $S$:

$$S = A_{22} - A_{21} A_{11}^{-1} A_{12}. \quad (8)$$

Recall that $S$ is nonsingular if $A_{11}$ and $A$ are nonsingular; if $A$ is strongly regular then so are $A_{11}$ and $S$. Finally, let

$$E = \begin{bmatrix} I_{n_1} & -A_{21} A_{11}^{-1} A_{12} \end{bmatrix}, \quad F = \begin{bmatrix} I_{n_1} & -A_{21} A_{12} \\ A_{21} A_{11}^{-1} \\ I_{n_2} \end{bmatrix}. \quad (9)$$

From $A_{22} = \text{diag}(A_{11}, S)$, we deduce the following classical recursive factorization of the inverse of $A$ [19, p. 157]:

$$A^{-1} = F \begin{bmatrix} A_{11}^{-1} \\ S^{-1} \end{bmatrix} E.$$  

## 2.1 Properties of Sylvester’s displacement

The properties below show how to deduce, given a $\nabla |M, N|$-generator for $A$, a generator for various matrices related to $A$. All of them appear in follow immediately from [18, 19].

**Generation of the transpose.** Let $A, G, H$ be as in (2). By transposing the identity $MA - AN = GH^T$, we obtain

$$\nabla |N^T, M^T|^T = -HG^T,$$  

so that the pair $(-H, G)$ is a $\nabla |N^T, M^T|$-generator of $A^T$.

**Generation of products.** One has the following classical rule for generating matrix products [19, p. 10]:

$$\nabla |M, N|(|AB) = \nabla |M, *|A|B + A \nabla |*, N|B). \quad (10)$$

for any matrix $*$ of conforming dimensions. Applying this rule twice, we can straightforwardly deduce explicit formulas for generating products of three matrices:

**Lemma 1.** Let $A, G, H$ be as in (2) and, for two matrices $P_1$ and $P_2$, let

$$\tilde{A} = P_1 A P_2. \quad (11)$$

If $\nabla |M, N| (P_1) = G_{P_1} H_{P_1}^T$ and $\nabla |N, \tilde{N}| (P_2) = G_{P_2} H_{P_2}^T$ then

$$\nabla |M, \tilde{N}| (\tilde{A}) = G_{P_1} H_{P_2}^T + H_{P_2} G_{P_1}^{T}.$$  

As an example, let us mention three special cases which we will use later: assuming $M, N \in \{ Z_{n,0}, Z_{n,0}^T \}$, let first

$$(P_1, P_2) = (I_n, I_n) \quad \text{and} \quad (M, N) = (M, N^T).$$

Then obviously $\nabla |M, M| (P_1)$ is zero and, using the facts that $Z_{n,0} = I_n$ and $J_n Z_{n,0} J_n = Z_{n,0}$ (see [19, p. 24]), we deduce that $\nabla |N, \tilde{N}| (P_2)$ is zero as well. Consequently, since $J_n$ is symmetric, applying (12) yields

$$\nabla |M, N^T| (A_{11}) = G(J_n H)^T. \quad (13a)$$

Similarly, exchanging the roles of $P_1$ and $P_2$ yields

$$\nabla |M^T, N^T| (J_n A_{11}) = (J_n G)^T H^T. \quad (13b)$$

while taking $P_1 = P_2 = J_n$ gives

$$\nabla |M^T, N^T| (J_n A_{11}) = (J_n G)(J_n H)^T. \quad (13c)$$

**Generation of submatrices.** From (2) and (6) and the partitioning into blocks we deduce that, for $i, j \in \{ 1, 2 \}$, submatrix $A_{ij}$ satisfies the following matrix equation

$$\nabla |M_{ij}, N_{ij}| (A_{ij}) = G_{ij} H_{ij}^T, \quad (14)$$

where, in particular (see for example [18, Proposition 4.4]),

$$G_{11} = |G_{11} - U_1 A_{11} U_2| \in K^{n_1 \times (n + \mu + \nu)}, \quad (15a)$$

$$H_{11} = |H_1 A_{12} V_2 V_1| \in K^{n_1 \times (n + \mu + \nu)}. \quad (15b)$$

**Generation of Schur complements.** By combining [18, Proposition 4.5] with (6), we have the following description of the structure of the Schur complement $S$ of $A_{11}$ in $A$:

$$\nabla |M_{22}, N_{22}| (S) = G_S H_S^T. \quad (16)$$
with $G_s$ and $H_s$ the two matrices in $K^{n_2 \times (n + \mu + \nu)}$ given by

$$G_s = [G_{2} - A_{22}A^{-1}_{12}G_{1}A_{22}A^{-1}_{12}U_1 - SU_2], \quad (17a)$$

$$H_s = [H_2 - A_{22}T_{12}A^{-1}_{12}T_{12} | S_{2}T_{2}A_{12}^{-1}T_{12} | \nu_1]. \quad (17b)$$

When the operator matrices $M$ and $N^\ast$ are lower triangular, one has $\mu = \nu = 0$ and the above formulas for generating the Schur complement can thus be simplified as follows (see [8, Theorem 2.3], [14, Lemma 3.1], [19, §8.4]):

$$G_s = G_{2} - A_{22}A_{12}^{-1}G_{1}, \quad H_s = H_{2} - A_{22}T_{12}A^{-1}_{12}T_{12}. \quad (18)$$

### 2.2 Computing with basic structures

We conclude our preliminaries by reviewing three basic invertible displacement operators that we shall repeatedly use in the sequel, as well as some associated cost functions. Here we assume that (2) holds in the rectangular case, that is, for $A \in K^{n \times m}$, $G \in K^{m \times n}$, and $H \in K^{n \times n}$; this assumption will allow us to handle off-diagonal blocks in Section 4. Recall also that $\nabla \{M, N\}$ is invertible if and only if the spectra of $M$ and $N$ are disjoint [19, p. 123].

#### Cauchy-like structure

For $x \in K^n$ and $y \in K^m$, assume

$$M = D(x), \quad N = D(y), \quad x_i \neq y_j \text{ for all } (i, j). \quad (19a)$$

Then $\nabla \{M, N\}$ is invertible and it is known [7] (see also [19, p. 8] and [20, Lemma 2.1]) that (2) is equivalent to

$$A = \sum_{i,j} D(g_{ij})C(x, y)D(h_{ij}), \quad (19b)$$

with $C(x, y)$ the $n$ by $m$ Cauchy matrix $[1/(x_i - y_j)]_{i,j}.$

#### Vandermonde-like structure

For $x \in K^n$, assume now

$$M = D(x), \quad N = Z_{m,0}, \quad x_i \neq 0 \text{ for all } i. \quad (20a)$$

Then $\nabla \{M, N\}$ is invertible and, in this case, $A$ can be recovered as follows (see [19, Example 4.4.6(d)]):

$$A = \sum_{i,j} D(x^{-1}, g_{ij})V(x^{-1}, m)U(h_{ij}), \quad (20b)$$

where, for $x \in K^n$, $V(x, m)$ is the $n$ by $m$ Vandermonde matrix whose $(i, j)$ entry equals $x^{i-1}$, and $U(h_{ij})$ is the $m$ by $m$ upper triangular Toeplitz matrix whose first row is $h_{ij}^T$.

#### Hankel-like structure

Assume finally that

$$M = Z_{n,1}, \quad N = Z_{n,0}. \quad (21a)$$

Since $Z_{n,1}$ and $Z_{n,0}$ have disjoint spectra, $\nabla \{M, N\}$ is invertible. In addition, we can recover $A$ as follows:

$$A = \sum_{j=1}^{m} T_{n \times m}(g_{j})L(h_{1})J_{m}. \quad (21b)$$

where, for $x \in K^n$, $T_{n \times m}(x)$ is the $n$ by $m$ Toeplitz matrix $[x_{i+(i-j+m) \text{ mod }n}]_{i,j}$, and where $L(h_{1})$ is the $m$ by $m$ lower triangular Toeplitz matrix whose first column is $h_{1}$. (A proof of (21b) is given in Appendix A.)

#### Cost functions

Our algorithms in the next sections will essentially require the ability to efficiently evaluate products of the form $Av$ and $A^T v$, where $A$ has one of the three basic structures above, $m$ is of the same order of $n$, and $v$ consists of one or several vectors.

In order to relate the costs of our algorithms in Section 4 to the costs of such products, we introduce the following functions. For the Cauchy-like structure (19a), let $MM_C : \mathbb{R}^{n_2 \times n_2} \to \mathbb{R}^{n_2}$ be such that, for $A \in \mathbb{R}^{n \times n}$ given by the right-hand side of (19b) and $v \in \mathbb{R}^{n_2}$, the products $Av$ and $A^T v$ can be computed using at most $MM_C(A, n, \beta)$ operations in $K$. We define the functions $MM_V$ and $MM_H$ in a similar way for, respectively, the Vandermonde-like and Hankel-like structures. Also, when $\beta = \alpha$ we shall simply write $MM_*(A, n, \beta)$ for $\cdot \in \{V, H\}$.

Following [6, p. 242], we write $M(n)$ for the cost of multiplying two polynomials of degree less than $n$ over $\mathbb{R}[x]$, and we assume that $M(n)$ is “superlinear,” that is, $M(n)/n$ is nondecreasing.

It is known (see for example [19]) that $C(x, y)$ is $C(x, y)$ and that multiplying $C(x, y), V(x, n),$ or $V(x, n)T$ by a vector can be done in time $O(M(n) \log(n))$ via (transposed) multipoint evaluation. Hence by a straightforward application of the summation formulas (19b), (20b), and (21b), one has

$$MM_*(A, n, 1) \in O(\alpha(M(n) \log(n)))$$

and for $\cdot \in \{V, H\}$,

$$MM_*(A, n, 1) \in O(\alpha(M(n))). \quad (23)$$

#### 3. PROPERTIES OF SPECIFIED GENERATORS OF THE MATRIX INVERSE

##### 3.1 Recovery after matrix transformations

We recalled in Section 2 some formulas for generating the matrix $A \in \{A^T, P, A_P\}$ from some generators of the matrix $A$. Conversely, we give in the theorem below some formulas for recovering specified generators of the inverse of $A$ from specified generators of the inverse of $A$.

**Theorem 1.** Let $A \in K^{n \times n}$ be invertible and let $G, H \in K^{n \times n}$ and $Y, Z \in K^{n \times n}$ be as in (2) and (3). Let $A \in K^{n \times n}$ be invertible and, for $G, H \in K^{n \times n}$, $\beta \geq \alpha$, define

$$\tilde{Y} = -A^{-1}G, \quad \tilde{Z} = A^{-T}H.$$

Then

- for $\tilde{A} = A^T$ and $(\tilde{G}, \tilde{H}) = (-H, G)$, one has
  $$Y = -\tilde{Z}, \quad Z = \tilde{Y};$$
for $\bar{A} = P_1 A P_2$ with $P_1, P_2 \in \mathbb{K}^{\alpha \times \alpha}$ invertible, and for $G, H$ as in (12), one has

$$Y = P_2 \bar{Y}^{-\alpha}, \quad Z = P_1 T Z^{-\alpha}. \quad \Box$$

Proof. In the first case, $Y = -(A^{-T}H)(-H) = A^{-T}H = Z$ and $\bar{Z} = (A^T)^{-T}G = A^{-1}G = -Y$. Now, in the case where $\bar{A} = P_1 A P_2$ Lemma 1 implies that the first $\alpha$ columns of $\bar{Y}$ are $Y^{-\alpha} = -(P_1 A P_2)^{-1} P_1 G = P_2^T Y$. Similarly, the first $\alpha$ columns of $\bar{Z}$ are $Z^{-\alpha} = (P_1 A P_2)^{-T} P_2^T H = P_1 T Z$. \quad \Box

For example, when $P_1, P_2 \in \{I_n, J_n\}$, it follows from (12) that $\beta = \alpha$. Consequently, Theorem 1 yields

$$(Y, Z) = (J_n Y, Z) \quad \text{if} \quad \bar{A} = A J_n, \quad (25a)$$

$$(Y, Z) = (Y, J_n Z) \quad \text{if} \quad \bar{A} = J_n A, \quad (25b)$$

$$(Y, Z) = (J_n \bar{Y}, J_n \bar{Z}) \quad \text{if} \quad \bar{A} = J_n A J_n. \quad (25c)

Reduction to basic displacements. A first consequence of Theorem 1, when it comes to computing specified inverse generators, is that the nine possible displacements defined in (1) can be reduced to the three basic ones shown in (4).

First, it follows from (13a) and (25a) that the case $N = Z_{m,\varphi}$ reduces to the case $N = Z_{1,\varphi}$. Similarly, (13b) and (25b) imply that the case $M = Z_{m,\varphi}$ reduces to the case $M = Z_{m,\psi}$. We thus are left with the four cases defined by

$$M \in \{D(x), Z_{m,\varphi}\} \quad \text{and} \quad N \in \{D(y), Z_{m,\psi}\}.$$  

Using (9) to further reduce the case where $M = Z_{m,\varphi}$ and $N = D(y)$ to the case where $M = D(y)$ and $N = Z_{m,\psi}$.

Due to the nature of the transformations applied to the $n \times \alpha$ generators (sign changes, permutations), the three reductions done so far imply an extra cost of only $O(\alpha n)$ operations in $K$.

To reach (4) it remains to zero out the scalars $\varphi$ and $\psi$. This can be done without transforming $A$, but only its displacement: for example, by combining the obvious identity

$$Z_{m,\varphi} = Z_{m,0} + \varphi e_{n,1} e_{n,1}^T,$$

with $\nabla D(x), Z_{m,\varphi}^T(A) = G H^T$ and $\nabla Z_{m,\varphi} (Z_{m,\varphi}^T)(A) = G H^T$, we arrive at, respectively,

$$\nabla D(x), Z_{m,0}^T(A) = \bar{G} H^T \quad (i)$$

with $\bar{G} = [G(\varphi e_{n,1})] H = [H|A e_{n,1}]$, and

$$\nabla Z_{m,0} (Z_{m,0}^T)(A) = G \bar{H}^T \quad (ii)$$

with $\bar{G} = [G|\varphi e_{n,1}] A e_{n,1}$ and $\bar{H} = [H|A^T e_{n,1} \varphi e_{n,1}]$. The last column or row of $A$ needed to set up the matrices $\tilde{G}$ and $\tilde{H}$ can be computed in $O(\alpha M(n) \log(n))$ —case (i)— or $O(\alpha M(n))$ —case (ii)— field operations from the explicit bilinear expressions of $A$ given in [19]. Examples 4.4.4 and 4.4.6(d)). Due to the shape of $\bar{G}, H$ above, extracting the first $\alpha$ columns of $\bar{Y} = A^{-1} G$ and $\bar{Z} = A^{-1} H$ in time $O(\alpha n)$ then yields the desired specified inverse generator $(Y, Z)$.

Reduction to strong regularity. Theorem 1 further allows to restrict to matrices that are not only invertible but strongly regular. Strong regularity, which is needed in order to apply Theorem 2 recursively, is classically obtained by preconditioning $A$ into $\bar{A} = P_1 A P_2$ with two random structured matrices $P_1$ and $P_2$ (see [19, §5.6]). Thus, one may generate $\bar{A}$ as in Lemma 1, then compute an associated specified generator $(Y, Z)$ of its inverse, and finally recover via Theorem 1 a specified generator $(Y, Z)$ of the inverse of $A$.

Let $r_1$ and $r_2$ be two random vectors in $\mathbb{K}^\alpha$ and whose first entry is one. Then, applying the rules of [19, p. 167], possible preconditions for each of the three basic displacements of (4) are as follows (with $x, y \in \mathbb{K}^\alpha$ and $x_i \neq 0$, $y_i \neq 0$, for all $i$):

$$\begin{array}{ccc}
M & N & P_1 & P_2 \\
\tilde{D}(x), \tilde{D}(y) & \tilde{C}(x, x) \tilde{D}(r_1) & \tilde{C}(y, y) \tilde{D}(r_2) \\
\tilde{D}(x), \tilde{Z}_{m,0}^T & \tilde{C}(x, x) \tilde{D}(r_1) & \tilde{L}(r_2) \\
\tilde{Z}_{m,0}, \tilde{Z}_{m,0}^T & \tilde{U}(r_1) & \tilde{L}(r_2) \\
\end{array}$$

For all these cases, one may check that the structure of $A$, $P_1$, and $P_2$ allows to prepare $(\tilde{G}, \tilde{H})$ in Lemma 1 and to recover $(Y, Z)$ in Theorem 1 in time $O(\alpha M(n))$ or $O(\alpha M(n) \log(n))$.

3.2 Recursive factorization formula

Theorem 2. Let $A \in \mathbb{K}^{n \times \alpha}$ be nonsingular and generated by $G$ and $H$ as in (2). Assume that $A_{11}$ is nonsingular as well, that it is generated by $G_{11}$ and $H_{11}$ as in (15), and let

$$Y_{11} = -A_{11}^{-1} G_{11}, \quad Z_{11} = A_{11}^{-1} H_{11}.$$  

Assume further that the Schur complement $S$ of $A_{11}$ in $A$ is generated by $G_5$ and $H_5$ as in (17), and let

$$Y_5 = -A_5^{-1} G_5, \quad Z_5 = A_5^{-1} H_5.$$  

Then the matrices $Y$ and $Z$ in (3) satisfy

$$Y = E \left[ \begin{array}{c} Y_{11}^\alpha \\ Y_5^\alpha \end{array} \right], \quad Z = E^T \left[ \begin{array}{c} Z_{11}^\alpha \\ Z_5^\alpha \end{array} \right],$$

where $E$ and $F$ are the elimination matrices defined in (7).

Proof. Using (5) and (8), we obtain

$$-A^{-1} G = F \left[ \begin{array}{c} -A_{11}^{-1} G_1 \\ -S^{-1} (G_2 - A_2 A_{11}^{-1} G_1) \end{array} \right].$$

It follows from (15a) and (17a) that $G_1 = G_{11}^\alpha$ and that $G_2 - A_2 A_{11}^{-1} G_1 = G_{21}^\alpha$. The expression claimed for $Y = -A^{-1} G$ then follows from applying the rule $A(B^{-\alpha}) = (AB)^{-\alpha}$ twice, and from the definitions of $Y_{11}$ and $Y_5$. The expression for $Z$ can be obtained in a similar way, using (15b) and (17b).

A first consequence of this theorem is a “compressed” analogue of the classical recursive factorization formula (8):

$$YZ^T = F \left[ \begin{array}{c} Y_{11}^\alpha \\ Y_5^\alpha \end{array} \right] \left[ \begin{array}{c} Z_{11}^\alpha \\ Z_5^\alpha \end{array} \right]^T E.$$

A second consequence of Theorem 2 is that, for $A$ strongly regular, we immediately get a recursive algorithm $\hat{a}$ in MDA whose key steps are the computation of $(G_{11}, H_{11})$ and $(G_5, H_5)$:

Given generators $G, H$ of length $\alpha$ for $A$,

- Compute a generator $(G_{11}, H_{11})$ for $A_{11}$ using (15);
- Recursively, compute $(Y_{11}, Z_{11}) = (-A_{11}^{-1} G_{11}, A_{11}^{-1} H_{11});$
- Compute a generator $(G_5, H_5)$ for $S$ using (17);
we obtain the following general algorithm:

Recursive, compute $(Y_5, Z_5) = (-S^{-1}G_5, S^{-T}H_5)$;

Compute $(-A^{-1}G, -A^{-T}H)$ from the first $\alpha$ columns of $Y_1, Y_5, Z_11, Z_5$, using Theorem 2.

4. ALGORITHMS FOR LOWER TRIANGULAR OPERATOR MATRICES $M$ AND $N^T$

In order to cover simultaneously the three displacements in (4) to which we have previously reduced, we assume in this section that both operator matrices $M$ and $N^T$ are lower triangular.

This assumption implies in particular that the blocks $M_{12}$ and $N_{21}$ in (6) are zero, so that their respective ranks $\mu$ and $\nu$ satisfy $\mu = \nu = 0$. From (15) it then follows that the submatrix $A_{11}$ satisfies

$$\nabla[M_{11}, N_{11}](A_{11}) = G_1H_1^T. \quad (27)$$

Thus, some generators of length at most $\alpha$ for $A_{11}$ can be read off the first $n_1$ rows of some generators of length at most $\alpha$ for $A$.

Assuming that $A_{11}$ is invertible, consider now the associated specified generators of $A_{11}$, that is,

$$Y_1 = -A_{11}^{-1}G_1, \quad Z_1 = A_{11}^{-T}H_1. \quad (28)$$

Combining the two identities in (28) with the explicit Schur complement generation formulas in (17) and (18) yields

$$\nabla[M_{22}, N_{22}](S) = (G_2 + A_2Y_1)(H_2 - A_1^{T}Z_11)^T. \quad (29)$$

In other words, the precise specification of the above generators of the inverse of $A_{11}$ can be exploited to simplify even further the generators of the Schur complement. In [4, Proposition 1], Cardinal had already noted this formula but only for the Cauchy-like structure ($M$ and $N$ diagonal).

Now, if we assume further that $A$ is strongly regular (which, if randomization is allowed, makes sense in view of the probabilistic reductions to strong regularity shown in Section 3.1), we obtain the following general algorithm:

**Algorithm GenInvLT**

**Input:** $M, N \in \mathbb{K}^{n \times n}$ and $G, H \in \mathbb{K}^{n \times n}$ such that $M$ and $N^T$ are lower triangular, and $\nabla[M, N](A) = G^T$.

**Assumptions:** $A$ is strongly regular, $m_{10} \neq n_{10}$ for all $(i, j)$.

**Output:** $Y = -A^{-1}G$ and $Z = A^{-T}H$.

if $n = 1$ then

Evaluate the dot product $GH^T$;

Deduce the scalar $A$;

$Y := -A^{-1}G, \quad Z := A^{-T}H$;

else

$n_1 := \lfloor n/2 \rfloor, \quad n_2 := \lceil n/2 \rceil$;

$G_{11} := G_1; \quad H_{11} := H_1$;

$(Y_{11}, Z_{11}) := \text{GenInvLT}(M_{11}, N_{11}, G_{11}, H_{11})$;

$G_2 := G + A_2Y_{11}; \quad H_2 := H_2 - A_1^{T}Z_{11}$;

$(Y_5, Z_5) := \text{GenInvLT}(M_{22}, N_{22}, G_2, H_2)$;

$Y := \begin{bmatrix} y_{11} - A_{11}^{-1}A_{21}^{T} y_5 \end{bmatrix}, \quad Z := \begin{bmatrix} z_{11} - A_{11}^{-1}A_{21}^{T} z_5 \end{bmatrix}$.

fi;

return $(Y, Z)$.

**THEOREM 3.** Algorithm GenInvLT is correct.

**Proof.** When $n = 1$, the assumption on $M$ and $N$ implies that $A$ is the scalar $(\sum_{i=1}^{n} g_i h_i) / (m_{11} - n_{11})$. Correctness then follows immediately in this case. Assume now that $n > 1$ and, in order to proceed by induction, assume correctness for $n' < n$. The matrix $A_{11}$ is strongly regular (since $A$ is) and it satisfies (27), where, by assumption $M_{11}$ and $N_{11}$ are both lower triangular and with disjoint diagonals. Since $n_1 < n$, the induction assumption then implies that the pair $(Y_{11}, Z_{11})$ returned by the first recursive call is precisely $(-A_{11}^{-1}G_1, A_{11}^{-T}H_1)$. Therefore, the computed pair $(G_5, H_5)$ satisfies (29), where, by assumption, $S$ is strongly regular (since $A$ is) and where $M_{22}$ and $N_{22}$ are both lower triangular and have disjoint diagonals. Since $n_2 < n$, the induction assumption implies that the pair $(Y_5, Z_5)$ returned by the second recursive call is exactly $(-S^{-1}G_5, S^{-T}H_5)$. The conclusion then follows from Theorem 2. \(\square\)

To implement Algorithm GenInvLT and bound its cost, all we need is to be able to evaluate the four matrix products

$$A_21 Y_{11}, \quad A_{12}^{-1} Z_{11}, \quad A_{11}^{-1} A_{21} Y_5, \quad A_{11}^{-1} A_{21}^{T} Z_5. \quad (30)$$

In the next subsections, we study the evaluation of those expressions for each of three basic structures of the Cauchy, Vandermonde, and Hankel types. That requires in each case a detailed analysis of the structure of the matrices $A_{11}^T, A_{12}, A_{21}$, and their transposes. Since in (30) there are two ways of parenthesizing the products of three matrices, we will also study the structure of $A_{11}^{-1} A_{21}$ and $(A_{12} A_{21}^{-1})^T$. The parenthesizations $(A_{11}^{-1} A_{12}) Y_5$ and $(A_{12} A_{21}^{-1})^T Z_5$ will be referred to as “Cardinal’s trick” later on, as they have been initially used in [4] for the Cauchy-like case.

4.1 Application to Cauchy-like matrices

We consider here the specialization of Algorithm GenInvLT to the Cauchy-like structure defined in (19a). Partitioning the two vectors $x$ and $y$ conformally with $A$ yields

$$x = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, \quad y = \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}, \quad x_1, y_1 \in \mathbb{K}^{n_1}, \quad x_2, y_2 \in \mathbb{K}^{n_2}.$$

**LEMMA 3.** Let the matrices $A, G, H, Y_11, Z_{11}, G_5, H_5$ be as in Algorithm GenInvLT. Then

- $\nabla[D(x_i), D(y_j)](A_{ij}) = G_i H_j^T$ for $1 \leq i, j \leq 2$,
- $\nabla[D(y_1), D(x_1)](A_1^{-T}) = Y_11 Z_11^T$,
- $\nabla[D(y_2), D(x_1)](A_2^{-1} A_1) = -Y_11^T H_2^T$,
- $\nabla[D(x_2), D(x_1)](A_1^{-1} A_2) = G_5^T Z_11^T$.

**Proof.** Since $D(x)$ and $D(y)$ are diagonal, all their off-diagonal blocks are zero, and the first identity follows from (2). To get the second identity, it suffices to pre- and postmultiply by $A_1^{-1}$ both sides of the first identity for $(i, j) = (1, 1)$, and then to use the specification of $Y_{11}$ and $Z_{11}$. Using the multiplication rule (10), we deduce further from the first identity for $(i, j) = (1, 2)$ and from the second one that

$$\nabla[D(y_1), D(y_2)](A_1^{-1} A_2) = Y_11 Z_11^T A_1^{-1} A_2^{-1} G_5^T H_2^T = Y_11 Z_11^T A_1^{-1} - H_2^T,$$

which by definition of $H_5$ equals $-Y_11^T H_2^T$. Similarly,

$$\nabla[D(x_2), D(x_1)](A_2^{-1} A_1) = G_2 H_1^T A_1^{-1} A_2^{-1} H_2^T = (G_2 A_1^T Y_{11}) Z_{11} = (G_2 + A_2 Y_{11}) Z_{11},$$

which by definition of $G_5$ equals $G_5 Z_{11}^T$. \(\square\)
THEOREM 4. Let $n$ be a power of two and $M, N \in \mathbb{K}^{n \times n}$ be as in (19a). Then Algorithm GenInvLT requires at most
\[3 \log(n) \text{MM}_C(\alpha, n) + O(\alpha n \log(n))\]
field operations. If, in addition, the set \(\{x_1, \ldots, x_n, y_1, \ldots, y_n\}\) has cardinality $2n$ then this bound drops to
\[2 \log(n) \text{MM}_C(\alpha, n) + O(\alpha n \log(n)).\]

PROOF. When $n = 1$, $A = \left(\sum_{i=1}^n g_i A_{11}\right)/(m_{11} - \eta_{11})$. Hence $A^{-1}$ can be computed using $2a + 1$ operations in $\mathbb{K}$, and the cost for $n = 1$ is $C(a, 1) = 4a + 2$. Consider now the case $n \geq 2$. Using Lemma 3 together with (9), we see that the matrices $A_{11}^{-1}$, $A_{12}$, $A_{21}$, and their transposes are all of the Cauchy-like structure defined in (19a). Furthermore, for each of them a generator of length at most $\alpha$ can deduced in time $O(\alpha n)$ from the quantities computed by Algorithm GenInvLT. Consequently, one can compute $A_{11}^T Y_{11}$, $A_{12}^T Z_{11}$, $A_{11}^{-1} (A_{12}^T Y_{11})$, and $A_{11}^{-1} Z_{11}^T Z_{12}$ via six applications, in dimension $n/2$, of the reconstruction formula (19b) to vectors in $\mathbb{K}^{n/2}$. Finally, Algorithm GenInvLT uses $2a n$ additions to deduce $G_{\alpha}, H_{\alpha}$, and the upper part of $Y$ and $Z$. Overall, the cost for $n \geq 2$ thus satisfies
\[C(\alpha, n) \leq 2 C(\alpha, n/2) + 6 \text{MM}_C(\alpha, n/2) + \alpha n\]
for some constant $k$. The superlinearity of $\text{MM}_C(\cdot, n)$ then yields our first bound.

Assume now that the $x_i$ and $y_i$ are $2n$ pairwise distinct values. From Lemma 3 the reconstruction formula (19b) can then be applied directly to $A_{11}^{-1} A_{12}$ and to the transpose of $A_{21} A_{11}^T$, in order to compute $(A_{11}^{-1} A_{12})^T Y_{12}$ and $(A_{21} A_{11}^{-1})^T Z_{12}$. This reduces the number of reconstructions from six to four, whence the second cost bound.

4.2 Application to Vandermonde-like matrices

Let us now focus on the cost of Algorithm GenInvLT when $M$ and $N$ correspond to the Vandermonde-like structure (20a). We assume $x$ to be partitioned as in the previous section.

LEMMA 4. Let the matrices $A, G, H, Y_{11}, Z_{11}, G_{\alpha}, H_{\alpha}$ be as in Algorithm GenInvLT. Let also $w_{11}$ be the last column of $A_{11}$ and $v_{12}$ be the first row of $A_{11}^T A_{12}$. Then
\[
\begin{align*}
\nabla [D(x), Z_{11}^T, 0] & (A_{12}) = G_{11} H_{11}^T + w_{11} e_{n_{12}, 1}, \\
\nabla [D(x), Z_{11}, 0] & (A_{21}) = G_{21} H_{21}^T, \\
\nabla [Z_{11}, 0, D(x)] & (A_{11}^T) = Y_{11} Z_{11}^T, \\
\n\nabla [D(x), D(x)] & (A_{21} A_{11}^{-1}) = G_{21} Z_{11}^T, \\
\n\nabla [Z_{11}, Z_{n_{12}, 0}] & (A_{11}^{-1} A_{12}) = -Y_{11} H_{11}^T + e_{n_{11}, 1} (e_{n_{12}, 1} + v_{12})^T.
\end{align*}
\]

PROOF. In this case, the upper-right block of $N$ satisfies $N_{12} = e_{n_{11}, n} e_{n_{12}, 1}^T$. Hence we deduce from (2) that
\[
\nabla [D(x), Z_{11}, 0] (A_{21}) = G_{21} H_{21}^T + A_{21} e_{n_{11}, n} e_{n_{12}, 1}^T \text{ and the first identity follows from the definition of vector } w_{11}.
\]

The second to fourth identities are obtained in the same way as in the proof of Lemma 3. Let us now verify the last identity, which displays the structure of the product $A_{11}^{-1} A_{12}$. First, applying the techniques of Lemma 3, we deduce that
\[
\nabla [Z_{11}, Z_{n_{12}, 0}] (A_{11}^{-1} A_{12}) = -Y_{11} H_{11}^T + e_{n_{11}, 1} e_{n_{12}, 1}^T.
\]

Then, using (26) with $(\varphi, n) = (1, n)$ together with the definition of $v_{12}$ yields the announced expression.

THEOREM 5. Let $n$ be a power of two and $M, N \in \mathbb{K}^{n \times n}$ be as in (20a). Then Algorithm GenInvLT requires at most
\[3 \log(n) \text{MM}_S(\alpha, n) + O(\alpha M(n) \log^2(n))\]
field operations. If, in addition, the set $\{x_1, \ldots, x_n\}$ has cardinality $n$ then this bound drops to
\[2 \log(n) \text{MM}_S(\alpha, n) + O(\alpha M(n) \log^2(n)).\]

PROOF. When $n = 1$, $A^{-1} = x_1/(\sum_{i=1}^n g_i A_{11})$, so that the cost is $C(a, 1) = 4a + 1$. Assume now that $n \geq 2$. Lemma 4 implies that $A_{12}, A_{21}$, and $A_{11}^{-1}$ share the same Vandermonde-like structure (20a) as $A$ and $A_{11}$. However, $A_{12}$ has displacement rank bounded by $\alpha + 1$ and computing its generator can be done at cost $O(\alpha M(n) \log(n))$ by applying (20b) to $A_{11}$. Hence, for $n \geq 2$,
\[
C(\alpha, n) \leq 2 C(\alpha, n/2) + 4 \text{MM}_V(\alpha, n/2) + 2 \text{MM}_V(\alpha + 1, n/2, \alpha) + \alpha \text{MM}_S(\alpha, n/2),
\]
for some constant $k$. From (22a) and the superlinearity of $M(n)$ and $M_S(\cdot, n)$, we then deduce the first cost bound.

If all the $x_i$ are distinct then, for $A_{12} A_{11}^{-1}$, we proceed as for the Cauchy-like case. For $A_{11}^T A_{12}$, note that $Z_{n_{11}} A_{11}^{-1} A_{12}$ is Hankel-like in the sense of (21a). Hence, one may first generate the latter matrix in time $O(\alpha M(n) \log(n))$ by obtaining the vector $v_{12}$ after two applications of (20b), then multiply by $Y_5$ using (21b), and re-apply a reflection. Thus,
\[
C(\alpha, n) \leq 2 C(\alpha, n/2) + \text{MM}_V(\alpha, n/2) + \text{MM}_V(\alpha + 1, n/2, \alpha) + \text{MM}_V(\alpha, n/2) + \text{MM}_S(\alpha + 1, n/2, \alpha) + \alpha \text{MM}_S(n, \log(n)),
\]
for some constant $k$, and the conclusion follows as before.

Note that unlike for the Cauchy-like case, if $a$ is small enough then in the cost bounds of Theorem 5 both summands have the same order of magnitude.

4.3 Extension to Hankel-like matrices

Finally, let us consider the Hankel-like structure defined by $M = Z_{n, 0}$ and $N = Z_{n, 0}^T$. Although $M$ and $N^T$ are lower triangular, Algorithm GenInvLT cannot be used directly in this case as the operator $\nabla [Z_{n, 0}, Z_{n, 0}^T]$ is not invertible. Covering such a structure, however, is interesting in particular as it yields an immediate extension to some Toeplitz-like matrices (see [19, Remark 5.4.4] and our Section 3.1).

To cope with the singularity of the displacement operator, some additional data, called irregularity set in [19, p. 136], are needed, which typically consist in “a few” entries of $A$. An irregular set for $\nabla [Z_{n, 0}, Z_{n, 0}^T]$ is given by the last row of $A$. Indeed, for $u^T = e_{n,n}^T A$ we see that (2) and (26) imply
\[
\nabla [Z_{n, 1}, Z_{n, 0}^T] (A) = [G | e_{n,n}] [H | u]^T,
\]
so that the matrix $A$ is Hankel-like in the sense of (21a), with displacement rank $\alpha + 1$. Consequently, the reconstruction formula (21b) can be used.

We need to exhibit an irregular set for $\nabla [Z_{n, 0}^T, Z_{n, 0}]$ too, because we shall multiply with inverses of Hankel-like matrices. A suitable choice here is $v^T = e_{n,T}^T A^{-1}$, the first row of the inverse of $A$: indeed, if $\nabla [Z_{n, 1}, Z_{n, 0}^T] (A^{-1}) = YZ^T$ then, recalling (13c), we may check that $Z_n A^{-1} Z_n$ satisfies an identity similar to (31); it is thus fully determined by: up to reflections, $Y, Z$, and its last row $v^T Z_n$.
The resulting adaptation of Algorithm GenInvLT to Hankel-like operator $\nabla[Z_{n,0}, Z_{n,0}^T]$ is as follows:

### Algorithm GenInvHL

**Input:** $G, H \in \mathbb{K}^{r \times n}$ such that $\nabla[Z_{n,0}, Z_{n,0}^T](A) = GH^T$, and $u = A^T e_{n,1}$ (the last row of $A$).

**Assumption:** $A$ is strictly regular.

**Output:** $Y = -A^{-1}G$, $Z = A^{-T}H$, and $v = A^{-T} e_{n,1}$ (the first row of $A^{-1}$).

- If $n = 1$ then
  
  $Y := -u^{-1}G; Z := u^{-1}H; v := u^{-1}$;

- else

  $n := \lfloor n/2 \rfloor; n_2 := \lfloor n/2 \rfloor$;

  $[u_1] := A e_{n,1}; [u_2] := u; Y \left[ Y_{11}, Z_{11} \right] := \text{GenInvHL}(G, H, u_1)$;

  $G := G + A_2^T Y_{11}; H := H - A_1^T Z_{11}$;

  $w := u_2 - A_2^T Y_{11}^T u_1;$

  $[Y_1, Z_1, v_1] := \text{GenInvHL}(G, H, w);$;

  $Y := \left[ Y_{11} - A_1^T Y_{11} Y_1, Y_1 ight]; Z := \left[ Z_1 - A_1^T Z_1 Y_1, Z_1 ight]$;

  $v := -w^T A_2^T v_1; v := [v_1 - A_1^T v_1 w; w]$.

- $f$;

  return $(Y, Z, v)$.

### Theorem 6. Algorithm GenInvHL is correct.

**Proof.** When $n = 1$, both $A$ and $v$ are reduced to the scalar $a_1$, and correctness is then straightforward. Assume now that $n > 1$ and, in order to proceed by induction, assume correctness for $n' < n$. The vector $u$ is split into $u_{21} \in \mathbb{K}^{n_2}$ and $u_{22} \in \mathbb{K}^{n_2}$. Similarly, the vector of coefficients of the last row of $A_{11}$ is split into $u_{11} \in \mathbb{K}^{n_1}$ and $u_{12} \in \mathbb{K}^{n_2}$. Hence $u_{11}$ equals $A_{11} e_{n,1}$ (that is, the vector of coefficients of the last row of $A_{11}$), $u_{21} = A_{21} e_{n,21}$, and $u_{22} = A_{22} e_{n,22}$. Recalling that $S = A_{22} - A_{21} A_{11}^T A_{12}$, we deduce that the vector $w_{21}$ computed by Algorithm GenInvHL satisfies $w_{21} = S^T e_{n,21}$ and thus is the vector of coefficients of the last row of $S$. Since the computation of $Y$ and $Z$ is unchanged in comparison to Algorithm GenInvLT, we still have $Y = -A^{-1}G$ and $Z = A^{-T}H$. All that remains is to prove that $v$ is actually the vector of coefficients of the first row of $A^{-1}$. By induction, $v_{11}$ and $v_{21}$ correspond to the first rows of $A_{11}^{-T}$ and $S^{-1}$, respectively, and $u_{21}$ and $v_{11}$ correspond to $A_{11}^{-T} e_{n,1}$ and $S^{-1} e_{n,1}$, respectively.

### Lemma 5.

Let $A, G, H, Y_{11}, Z_{11}, G_S, H_S, u_{11}$ be as in Algorithm GenInvHL. Recall that $u_{11}$ is the last row of the matrix $A_{11}$ and let $w_{11}$ be its last column. Then

- $\nabla[Z_{n,1}, Z_{n,1}^T] = G_S H^T + w_{11} e_{n,1}^T$.
- $\nabla[Z_{n,1}, Z_{n,1}^T] = G_S H^T - e_{n,1} u_{11}^T$.

### Theorem 7.

Let $n$ be a power of two and $M, N \in \mathbb{K}^{r \times n}$ be as in (21a). Then Algorithm GenInvHL requires at most

$$2 \log(n) MM(n, n) + O(\alpha \log(n)).$$

**Proof.** Proceed as for Lemma 3 and Lemma 4.

### 5. EXPERIMENTAL RESULTS

We have implemented the two variants of GenInvLT (with and without Cardinal’s trick) as well as the MBA algorithm for Sylvester’s displacement. Moreover, we have developed some code to handle Cauchy-like and Hankel-like structures.

For our experiments, we take $\mathbb{K} = \mathbb{F}_2$ with $p = 999999937$, which lets us measure the algebraic costs. Basic operations in $\mathbb{K}$ are provided by NTL, and we also use some code for fast polynomial arithmetic. All the computations are carried out on a desktop machine with an Intel® Core™ i7-2670QM 2 Duo processor at 2.66 GHz. Finally, generators $(G, H)$ are picked randomly, while operator matrices $D(x), D(y)$ are chosen in order to satisfy all the assumptions made on the algorithms.

Figure 1 shows computing times for inverting Cauchy-like matrices of displacement rank $\alpha = 10$ when $n$ is increasing. It appears that the computing time is quasi-linear with respect to $n$ for each method, and that the compression steps in MBA have negligible cost. Thus, the main difference explaining the various performances lies in the number of products “Cauchy-like matrix $\times$ vectors.” We have already seen in Theorem 4 that the choice in the parenthesizations leads to one variant in $3 \log(n) MM(\alpha, n)$ and, up to stronger conditions on the input, to another variant in $2 \log(n).MM(\alpha, n)$. Let us now estimate this cost for our implementation of the MBA algorithm. Generators for the Schur complement and the inverse of $A$ before the compression steps are computed using (10) according to the following parenthesizations: $X_{11} = A_{11}^{-T} A_{12}$, $S = A_{22} - A_{21} X_{11}$.

1.http://www.shoup.net/tt1/
MM superlinearity of $\alpha$, additional time due to subblocks having displacement rank (Cardinal's trick), which is in agreement with our analysis above.

The total cost seems quadratic in $\alpha$ and linear in $n$. It would be interesting to measure the memory gains brought by the free algorithm to a broader class of structured matrices, in addition to fast dense linear algebra) when

$$X_2 = A_{21}A_{11}^{-1},$$

and

$$A^{-1} = \begin{bmatrix} A_{21}^{-1} + (x_1 s^{-1}) x_2 & -x_1 s^{-1} \\ -s^{-1} x_2 & s^{-1} \end{bmatrix}.$$

Counting the costs of all these products using (23) and the superlinearity of $\text{MM}_C(\cdot, n)$ leads to a bound of $14 \text{MM}_C(\alpha, n)$ in the recurrence equation for the cost of MBA, which gives a total cost dominated by $14 \log(n) \text{MM}_C(\alpha, n)$. In Figure 1, we observe a speed-up around $4.6 \approx 14/3$ between MBA and our first variant (GenInvL), and around $6.7 \approx 14/2$ between MBA and the second variant (GenInvL + Cardinal’s trick), which is in agreement with our analysis above.

Moreover, we experimented with Hankel-like matrices in order to estimate the cost of row reconstruction and the additional time due to subblocks having displacement rank $\alpha + 1$ instead of $\alpha$ like in the Cauchy-like case. Timings are summarized in Table 1, where it appears that these costs become negligible when $\alpha$ is large enough. Indeed, they are linear in $\alpha$ as expected (see (22b) and Theorem 5) while the total cost seems quadratic in $\alpha$.

6. CONCLUSIONS

In this paper, we have extended Cardinal’s compression-free algorithm to a broader class of structured matrices, including not only the Cauchy-like type but also the Vandermonde, Hankel, and Toeplitz-like types. Our main conclusion is that this approach yields variants of the MBA algorithm that are simpler to analyze and implement, and, according to our first experiments, significantly faster in practice. However, this study calls for a number of extensions:

- On the practical side, we should first study the impact of stopping recursive calls (and reconstructing $A^{-1}$ explicitly via fast dense linear algebra) when $n \approx \alpha$. It would also be interesting to measure the memory gains brought by Cardinal’s extended approach over MBA.

- On the algorithmic side, although we have focused only on $O(\alpha^2 n)$ versions of MBA, it would be interesting to incorporate the matrix multiplication techniques of [3]. We should also study the impact of multiplicities in $x$ and $y$ on the cost bounds and adapt our work to structures like those of the Toeplitz + Hankel-like type.

7. ACKNOWLEDGMENTS

We thank Benoît Lacelle for providing a framework for structured matrices and the generator-compression subroutine used in our implementation of MBA, and Éric Schost for pointing out the code used for multipoint evaluation.

Theorem 8. Equation (21b) is correct.

Proof. The Hankel-like matrix $A \in \mathbb{K}^{n \times m}$ satisfies

$$Z_{n,1}A - AZ_{m,0}^T = GH^T.$$ 

By left-multiplying with $Z_{n,1}^T$, we deduce the following recurrence formula:

$$A = Z_{n,1}AZ_{m,0}^T + Z_{n,1}^TH^T.$$ 

We can now apply Theorem 4.3.6 from [19] to obtain that, for all integer $k$,

$$A = (Z_{n,1})^k A(Z_{m,0})^k + \sum_{l=0}^{k-1} (Z_{n,1})^{l+1} GH^T(Z_{m,0})^l.$$ 

As $(Z_{m,0})^l$ is the null matrix as soon as $l \geq m$, we can simplify the above equation:

$$A = \sum_{l=0}^{m-1} (Z_{n,1})^{l+1} GH^T(Z_{m,0})^l$$

$$= \sum_{l=0}^{m-1} (Z_{n,1})^{l+1} \left( \sum_{j=1}^{\alpha} g_j h_j^T \right) (Z_{m,0})^l$$

$$= \sum_{j=1}^{\alpha} \sum_{l=0}^{m-1} (Z_{n,1})^{l+1} g_j h_j^T (Z_{m,0})^l.$$ 

The inner sum is a sum of $m$ outer products. This can be rewritten as a product of two matrices $B \in \mathbb{K}^{n \times m}$ and $C \in \mathbb{K}^{m \times m}$ by taking $(Z_{n,1})^{l+1} g_j$ for column $m - l$ of $B$ and $h_j^T(Z_{m,0})^l$ for row $m - l$ of $C$. Thus, the $i$th row of $C$ is exactly $[0 \ldots 0 h_{j,i} \ldots 0]$ so that $C = [\mathbb{L}(h_j)]_{i \times m}$.

Finally, the last column of $B$ is $[g_{j,2} \ldots g_{j,n} g_{j,1}]^T$ and we can deduce its column $l$ by applying $Z_{n,1}^T$ to its column $l + 1$, that is by moving the elements of column $l + 1$ one location up (except for the first element which goes at bottom). This defines a Toeplitz matrix whose coefficient $(k, l)$ is $g_{j,1+(k-l+m)} \mod n$, which is $T^{n \times m}(g_j)$ by definition. □
