Abstract

We present several results on counting untyped lambda terms, i.e., on telling how many terms belong to such or such class, according to the size of the terms and/or to the number of free variables.

1 Introduction

This paper presents several results on counting untyped lambda terms, i.e., on telling how many terms belong to such or such class, according to the size of the terms and/or to the number of free variables. In particular, it gives results on the distribution of terms according to their number of free variables and explores properties of these distributions, especially through generating functions. In addition to the inherent interest of these results from the mathematical point of view, we expect that a knowledge on the distribution of terms will improve the implementation of reduction and that results on asymptotic distributions of terms will give a better insight of the lambda calculus. We show strong evidence for the claim that when the number m of free variables tends to infinity, the ratio "number of normal forms of size n over number of terms of size n" decreases and tends to 1. The results presented here are a milestone in describing probabilistic properties of lambda terms with answers to questions like: How does a random lambda term looks like? How does a random normal form look like? How to generate a random lambda term (a random normal form)?

Related works

Previous works on counting lambda terms were by O. Bodini et al. [2], R. David et al. [4] and J. Wang [13]. Related works are on counting types and/or counting tautologies [14, 9, 5, 10]. Complexity of rewriting was studied by Choppy et al. [3].

2 Untyped lambda terms with de Bruijn indices

> *I am dedicating this book to N. G. "Dick" de Bruijn, because his influence can be felt on every page. Ever since the 1960s he has been my chief mentor, the main person who would answer my question when I was stuck on a problem that I had not been taught how to solve.*
>
> Donald Knuth in preface of [11]

The λ-calculus [1] is a logic formalism to describe fonctions, for instance, the function $f \mapsto (x \mapsto f(f(x))$, which takes a fonction f and applies it twice. For historical reason, this function is written $\lambda\, f.\lambda\, x.f(fx)$, which contains the two variables f and x, bounded by λ.

In this paper we represent terms by De Bruijn indices [7], this means that variables are represented by numbers $\underline{1}, \underline{2}, ..., \underline{\mathsf{m}}, ...$, where an index, for instance $\underline{\mathsf{k}}$, is the number of λ, above the location of the index and below the λ that binds the variable, in a representation of λ-terms by trees. For instance, the term with variables $\lambda x.\lambda y.x\, y$ is represented by the term with de Bruijn indices $\lambda\lambda\underline{21}$. The variable x is bound by the top λ. Above the occurrence of x, there are two λ's, therefore x is represented by $\underline{2}$ and from the occurrence of y, we count just the λ that binds y; so y is represented by $\underline{1}$. In what follows we will call *terms*, the untyped terms[1] with de Bruijn indices. Let us call $\mathcal{T}_{n,m}$, the set of terms of size n, with m de Bruijn indices, i.e., with indices in $\mathcal{I}(m) = \{\underline{1}, \underline{2}, ..., \underline{\mathsf{m}}\}$. A term in $\mathcal{T}_{n,m}$, is either a de Bruijn index or an abstraction on a term with $m+1$ indices i.e., a term in $\mathcal{T}_{n,m+1}$ or an application of a term in $\mathcal{T}_{n,m}$ on a term in $\mathcal{T}_{n,m}$. We can write, using @ as the application symbol,

$$\mathcal{T}_{n+1,m} = \mathcal{I}(m) \uplus \lambda\mathcal{T}_{n,m+1} \uplus \biguplus_{k=0}^{n} \mathcal{T}_{n-k,m}@\mathcal{T}_{k,m}.$$

Moreover terms of size 1 are only made of de Bruijn indices, therefore

$$\mathcal{T}_{1,m} \quad = \quad \mathcal{I}(m).$$

From thiswe get:

$$\begin{aligned} T_{n+1,m} &= T_{n,m+1} + \sum_{k=0}^{n} T_{n-k,m}.T_{k,m} \\ T_{1,m} &= m \\ T_{0,m} &= 0 \end{aligned}$$

$T_{n,0}$ is the set of closed terms (terms with no non bound indices). Notice that

$$T_{n+1,m} \quad = \quad T_{n,m+1} + \sum_{k=1}^{n-1} T_{n-k,m}.T_{k,m}$$

[1] Roughly speaking, typed terms are terms consistent with properties of the domain and the codomain of the function they represent.

Let us illustrate this result by the array of closed terms up to size 5:

n	terms	$T_{n,0}$
1	none	0
2	$\lambda\underline{1}$	1
3	$\lambda\lambda\underline{1}, \lambda\lambda\underline{2}$,	2
4	$\lambda\lambda\lambda\underline{1}, \lambda\lambda\lambda\underline{2}, \lambda\lambda\lambda\underline{3}, \lambda(\underline{1}.\underline{1})$	4
5	$\lambda\lambda\lambda\lambda\underline{1}, \lambda\lambda\lambda\lambda\underline{2}, \lambda\lambda\lambda\lambda\underline{3}, \lambda\lambda\lambda\lambda\underline{4}, \lambda\lambda(\underline{1}.\underline{1}), \lambda\lambda(\underline{1}.\underline{2}), \lambda\lambda(\underline{2}.\underline{1}), \lambda\lambda(\underline{2}.\underline{2}),$ $\lambda(\underline{1}.\lambda\underline{1}), \lambda(\underline{1}.\lambda\underline{2}), \lambda((\lambda\underline{1}).\underline{1}), \lambda((\lambda\underline{2}).\underline{1}), \lambda\underline{1}.\lambda\underline{1}$	13

The equation that defines $T_{n,m}$ allows us to compute it, since it relies on entities $T_{i,j}$ where either $i < n$ or $j < m$. Figure 1 is a table of the first values of $T_{n,m}$ up to $T_{18,7}$. We are mostly interested by the sequence of sizes of the closed terms, namely $T_{n,0}$, in other words the first column of the table. The values of $T_{n,0}$ correspond to sequence **A135501** (see `http://www.research.att.com/~nudges/sequences/A135501`) due to Christophe Raffalli, which is the *number of closed lambda-terms of size n*. His formula for those numbers is more complex. He considers the values of the double sequence $f_{n,m}$. $T_{n,m}$ and $f_{n,m}$ coincide for $m = 0$, i.e., $T_{n,0} = f_{n,0}$.

$$
\begin{aligned}
f_{1,1} &= 1 \\
f_{0,m} &= 0 \\
f_{n,m} &= 0 \quad \text{if } m > 2n-1 \\
f_{n,m} &= f_{n-1,m} + f_{n-1,m+1} + \sum_{p=1}^{n-2} \sum_{c=0}^{m} \sum_{l=0}^{m-c} \binom{c}{m} \binom{l}{m-c} f_{p,l+c} f_{n-p-1,m-l}.
\end{aligned}
$$

He adds

> The last term is for the application where c is the number of common variables in both subterms. $f_{n,m}$ can be computed only using $f_{n',m'}$ with $n' < n$ and $m' \leq m + n - n'$.

Notice that he deals only with sequence $T_{n,0}$, whereas we consider the values for any value of m, from which we can expect to extract interesting informations. The main interesting statement we can draw from this is that considering lambda terms with explicit variables or considering lambda terms with de Bruijn indices makes no difference, at least when no β-reduction is taken into account. We feel that considering lambda terms with de Bruijn indices makes the task easier and produces more results.

3 The functions $m \mapsto T_{n,m}$

Due to properties of the generating function (see Section 5) we are not able to give a simple expression for the function $n \mapsto T_{n,m}$, so we focus on the function $m \mapsto T_{n,m}$. These functions are polynomial P_n^T, defined recursively as follows:

$$P_0^T(m) = 0 \quad (1)$$
$$P_1^T(m) = m \quad (2)$$
$$P_{n+1}^T(m) = P_n^T(m+1) + \sum_{k=1}^{n-1} P_k^T(m)\, P_{n-k}^T(m). \quad (3)$$

See Figure 2 for the first 18 polynomials. The degrees of those polynomials increase two by two and we can describe their leading coefficients and their second leading coefficients.

Proposition 1 *$deg(P_{2p-1}^T) = deg(P_{2p}^T) = p$.*

Proof: This is true for $P_1^T = m$ and $P_2^T = m+1$ which have degree 1. Assume the property true up to p. Note that all the coefficients of the P_n^T's are positive. In

$$P_n^T(m+1) + \sum_{k=1}^{n-1} P_k^T\, P_{n-k}^T,$$

the degree of $P_{n+1}^T(m)$ comes from the $P_k^T\, P_{n-k}^T$'s. Indeed, par induction the degree of $P_n^T(m+1)$ is $n \div 2$ which is less than $(n+1) \div 2$, therefore we can consider that $P_n^T(m+1)$ does not contribute to the degree of $P_{n+1}^T(m)$. Consider the degree of $P_k^T\, P_{n-k}^T$ according to the parity of n and k.

- $n = 2p+1$ **and** $k = 2h-1$**.** In this case, $p \geq h \geq 1$ and the degree of P_{2h-1}^T is h and the degree of $P_{2p+1-2h+1}^T$ is $p-h+1$, hence the degree of $P_{2h-1}^T\, P_{2p+1-2h+1}^T$ is $p+1$.
- $n = 2p+1$ **and** $k = 2h$**.** In this case, $p \geq h \geq 1$ and the degree of P_{2h}^T is h and the degree of $P_{2p+1-2h}^T$ is $p-h+1$, hence the degree of $P_{2h}^T\, P_{2p+1-2h}^T$ is $p+1$.
- $n = 2p$ **and** $k = 2h-1$**.** In this case, $p+1 \geq h \geq 1$ and the degree of P_{2h-1}^T is h and the degree of $P_{2p-2h+1}^T$ is $p-h+1$, hence the degree of $P_{2h-1}^T\, P_{2p+2-2h+1}^T$ is $p+1$.
- $n = 2p$ **and** $k = 2h$**.** In this case, $p+1 \geq h \geq 1$ and the degree of P_{2h}^T is h and the degree of P_{2p-2h}^T is $p-h$, hence the degree of $P_{2h}^T\, P_{2p-2h}^T$ is p. These products $P_{2h}^T\, P_{2p-2h}^T$ do not contribute to the degree of P_{2p+1}^T.

□

In what follows, for short, we write θ_{2q+1} and θ_{2q} the leading coefficients of P_{2q+1}^T and P_{2q}^T, τ_{2q+1} and τ_{2q} the second leading coefficients of P_{2q+1}^T and P_{2q}^T, and δ_{2q+1} the third leading coefficients ofP_{2q+1}^T. We also write, as usual, C_n the n^{th} Catalan number.

We define five generating functions.

$$\mathcal{O}d(z) = \sum_{i=0}^{\infty} \theta_{2i+1} z^i \qquad \mathcal{E}v(z) = \sum_{i=0}^{\infty} \theta_{2i} z^i$$

$$\mathcal{S}od(z) = \sum_{i=0}^{\infty} \tau_{2i+1} z^i \qquad \mathcal{S}ev(z) = \sum_{i=0}^{\infty} \tau_{2i+1} z^i$$

$$\mathcal{T}od(z) = \sum_{i=0}^{\infty} \delta_{2i+1} z^i.$$

Proposition 2 *The leading coefficients of P^T_{2q+1} are $\frac{1}{q+1}\binom{2q}{q}$, i.e., the Catalan numbers C_q.*

Proof: From Equation 3 and the last two steps of the proof of Proposition 1, we deduce the following relation :

$$\begin{aligned} \theta_{2q+1} &= \sum_{h=0}^{q-1} \theta_{2h+1}\, \theta_{2q-2h-1} \qquad \text{for } q \geq 1 \\ \theta_1 &= 0. \end{aligned}$$

We get:

$$\mathcal{O}d(z) = 1 + z\, \mathcal{O}d(z)^2.$$

which shows that

$$\mathcal{O}d(z) = \frac{1 - \sqrt{1-4z}}{2z}.$$

and $\mathcal{O}d = C(z)$, the generating function of the Catalan numbers. □

Proposition 3 *The leading coefficients of P^T_{2q} are $\binom{2q-1}{q}$, for $q \geq 1$.*

Proof: Without lost of generality, we assume that $\theta_0 = 0$. From Equation 3, we get, for $q \geq 1$,

$$\begin{aligned} \theta_{2q+2} &= \theta_{2q+1} + \sum_{k=0}^{2q+1} \theta_k\, \theta_{2q+1-k} \\ &= \theta_{2q+1} + \sum_{h=0}^{q} \theta_{2h}\, \theta_{2q+1-2h} + \sum_{h=0}^{q} \theta_{2h+1}\, \theta_{2q-2h} \\ &= \theta_{2q+1} + 2 \sum_{h=0}^{q} \theta_{2h}\, \theta_{2q-2h+1}. \end{aligned}$$

We get:

$$\mathcal{E}v(z) = z\mathcal{O}d(z) + 2\, z\mathcal{E}v(z)\mathcal{O}d(z),$$

hence

$$\mathcal{E}v(z) = \frac{z\mathcal{O}d(z)}{1-2z\mathcal{O}d(z)} = \frac{1-\sqrt{1-4z}}{2\sqrt{1-4z}} = \frac{\sqrt{1-4z}}{2(1-4z)} - \frac{1}{2}$$

which is the generating function of the sequence $\binom{2q+1}{q}$. □

Proposition 4 *The second leading coefficients of P^T_{2q+1} are $(2q-1)\binom{2(q-1)}{q-1}$.*

Proof: From the proof of Proposition 1, we see that the monomial of second highest degree of P_{2q+1} is made as the sum:

- of the monomial of highest degree of P_{2q},
- of the products of the monomials of highest degree from the P_i's with even indices and
- the products of monomials of highest degree with monomials of second highest degree from the P_i's with odd indices.

We get for $q \geq 1$:

$$\tau_{2q+1} \quad = \quad \theta_{2q} + \sum_{h=0}^{q} \theta_{2h}\theta_{2q-2h} + \sum_{h=0}^{q-1} \theta_{2h+1}\tau_{2q-2h-1} + \sum_{h=0}^{q-1} \tau_{2h+1}\theta_{2q-2h-1}.$$

We notice that $\tau_1 = 0$. Thereforewe get:

$$\mathcal{S}od(z) \quad = \quad \mathcal{E}v(z) + \mathcal{E}v(z)^2 + 2z\mathcal{O}d(z)\,\mathcal{S}od(z).$$

Then

$$\mathcal{S}od(z) = \frac{\mathcal{E}v(z) - \mathcal{E}v(z)^2}{1-2z\mathcal{O}d(z)} = \frac{z}{\sqrt{1-4z}(1-4z)} = \frac{z\sqrt{1-4z}}{(1-4z)^2}$$

which is the generating function of $(2q-1)\binom{2(q-1)}{q-1}$. □

Proposition 5 *The second leading coefficients of P^T_{2q} are $\tau_0 = 0$, $\tau_1 = 1$, $\tau_2 = 5$ and for $q \geq 3$,*

$$\tau_{2q} \;=\; 4^{q-1} + \frac{2(2q-5)(2q-3)(2q-1)}{3(q-2)}\binom{2(q-3)}{q-3}.$$

Proof: From Equation 3,we get

$$\begin{cases} \tau_{2q+2} & = & (q+1)\theta_{2q+1} + \tau_{2q+1} \\ & & +2\sum_{i=1}^{q} \theta_{2i-1}\tau_{2q-2i+2} + 2\sum_{i=1}^{q} \theta_{2i}\tau_{2q-2i+1} \\ \tau_0 & = & 0 \end{cases}$$

From the above induction, $\mathcal{S}ev$ fullfils the following functional equation:

$$\mathcal{S}ev(z) = z\mathcal{O}d(z) + z^2\mathcal{O}d'(z) + z\mathcal{S}od(z) + 2z\mathcal{O}d(z)\mathcal{S}ev(z) + 2z\mathcal{E}v(z)\mathcal{S}od(z).$$

Therefore

$$\begin{aligned}
\mathcal{S}ev(z) &= \frac{z\mathcal{O}d(z) + z^2\mathcal{O}d'(z) + z\mathcal{S}od(z) + 2z\mathcal{E}v(z)\mathcal{S}od(z)}{\sqrt{1-4z}} \\
&= \frac{(1-\sqrt{1-4z})}{2\sqrt{1-4z}} \\
&\quad + \frac{z}{1-4z} - \frac{1-\left(\sqrt{1-4z}\right)}{2\sqrt{1-4z}} \\
&\quad + \frac{z^2}{(1-4z)^2} \\
&\quad + \frac{z(1-\sqrt{1-4z})}{(1-4z)^2\sqrt{1-4z}} \\
&= \frac{z}{1-4z} + \frac{z^2}{(1-4z)^2} + \frac{z^2(1-\sqrt{1-4z})}{(1-4z)^2\sqrt{1-4z}} \\
&= \sum_{q=1}^{\infty} 4^{q-1}z^q + \sum_{q=2}^{\infty}(q-1)4^{q-2}z^q + \sum_{q=3}^{\infty} 2a_{q-3}z^q
\end{aligned}$$

where $(a_n)_{n\in\mathbf{N}}$ is sequence A029887 of the *On-Line Encyclopedia of Integer Sequences* whose value is:

$$\frac{(2n+1)(2n+3)(2n+5)}{3}C_n - (n+2)2^{2n+1}.$$

Hence

$$\begin{aligned}
\mathcal{S}ev(z) &= \sum_{q=1}^{\infty} 4^{q-1}z^q + \sum_{q=3}^{\infty} \frac{2(2q-5)(2q-3)(2q-1)}{3}C_{q-3}z^q \\
&= \frac{z}{1-4z} + \frac{z^2}{(1-4z)^2\sqrt{1-4z}}.
\end{aligned}$$

□

Proposition 6 *The third leading coefficients of P^T_{2q+1} are*

$$q\ 2^{2q-1} + \frac{q(q-1)(q-2)}{120}\binom{2q}{q} + \frac{(q+1)q(q-1)}{120}\binom{2(q+1)}{q+1}.$$

Proof: Since $deg(P^T_{2n}) = deg(P^T_{2n+1}) - 1$, the third coefficient is the sum of seven items, namely:

- the second coefficient of $\theta_{2q}\,(m+1)^q$, namely $q\theta_{2q}$,
- the first coefficient of $(m+1)^{q-1}$, namely τ_{2q},
- the sum of products of leading coefficients and second leading coefficients for even polynomials (twice),

- the sum of leading coefficients and third leading coefficients for odd polynomials (twice),
- the sum of second leading coefficients with second leading coefficients.

The formula gives:

$$\begin{aligned}\delta_{2q+1} &= q\,\theta_{2q} + \tau_{2q} + \sum_{i=0}^{q} \tau_{2i}\theta_{2q-2i} + \sum_{i=0}^{q} \theta_{2i}\tau_{2q-2i} + \\ &\sum_{i=0}^{q-1} \theta_{2i+1}\delta_{2q-2i-1} + \sum_{i=0}^{q-1} \delta_{2i+1}\theta_{2q-2i-1} + \sum_{i=0}^{q-1} \tau_{2i+1}\tau_{2q-2i-1},\end{aligned}$$

which gives the following equation on generating functions:

$$\begin{aligned}\mathcal{T}od(z) &= z\,\mathcal{E}v'(z) + \mathcal{S}ev(z) + 2z\mathcal{E}v(z)\mathcal{S}ev(z) + \\ &2z\,\mathcal{O}d(z)\mathcal{T}od(z) + z\,\mathcal{S}ev(z)^2.\end{aligned}$$

which yields:

$$\begin{aligned}\mathcal{T}od(z) &= \frac{z\,\mathcal{E}v'(z) + \mathcal{S}ev(z) + 2z\mathcal{E}v(z)\mathcal{S}ev(z) + z\,\mathcal{S}ev(z)^2}{1 - 2z\,\mathcal{O}d(z)} \\ &= \frac{1}{\sqrt{1-4z}}\left(\frac{z}{(1-4z)\sqrt{1-4z}} + \right. \\ &\qquad \frac{z}{1-4z} + \frac{z^2}{(1-4z)^2\sqrt{1-4z}} + \\ &\qquad \frac{1-\sqrt{1-4z}}{\sqrt{1-4z}}\left(\frac{z}{1-4z} + \frac{z^2}{(1-4z)^2\sqrt{1-4z}}\right) + \\ &\qquad \left.\frac{z^3}{(1-4z)^3}\right) \\ &= \frac{2z}{(1-4z)^2} + \frac{z^2+z^3}{(1-4z)^3\sqrt{1-4z}}.\end{aligned}$$

The first part corresponds to sequence A002699 which expression is $q\,2^{2q-1}$. $1/(1-4z)^3\sqrt{1-4z}$ corresponds to sequence A144395. Therefore the second part yields the expression

$$\frac{q(q-1)(q-2)}{120}\binom{2q}{q} + \frac{(q+1)q(q-1)}{120}\binom{2(q+1)}{q+1}.$$

□

Hence typically if we pose

$$\begin{aligned}\tau_{2q} &= 4^{q-1} + \frac{2(2q-5)(2q-3)(2q-1)}{3}C_{q-3} \\ \delta_{2q+1} &= q\;2^{2q-1} + \frac{(q+1)q(q-1)(q-2)}{120}C_q + \frac{(q+2)(q+1)q(q-1)}{120}C_{q+1}\end{aligned}$$

we have in general:

$$\begin{aligned} P^T_{2q}(m) &= (2q-1)C_{q-1}m^q + \tau_{2q}m^{q-1} + \ldots + T_{2q,0} \\ P^T_{2q+1}(m) &= C_q m^{q+1} + \frac{2q(2q-1)}{2}C_{q-1}m^q + \delta_{2q+1}m^{q-1} + \ldots + T_{2q+1,0} \end{aligned}$$

showing the prominent role of Catalan numbers. The relations for the other coefficients are more convoluted.[2]

It should be interesting to study the connection with the derivatives of the generating function of the Catalan numbers [12], namely $(1-\sqrt{1-4z})/2z$. The table below gives the coefficients of the polynomials P^T_n up to 13.

$n\backslash m^i$	m^8	m^7	m^6	m^5	m^4	m^3	m^2	m	1
1								1	0

A conjecture

Recall what we have computed:

coefficients	*generating functions*		*values*	*equivalents*
$P^T_{2q+1,q+1}$	$\mathcal{O}d(z)$	$\frac{1-\sqrt{1-4z}}{2z}$	C_q	$4^q\sqrt{\frac{1}{\pi q^3}}$
$P^T_{2q+1,q}$	$\mathcal{S}od(z)$	$\frac{z\sqrt{1-4z}}{(1-4z)^2}$	$(2q-1)\binom{2(q-1)}{q-1}$	$4^q\ \frac{1}{2}\ \sqrt{\frac{q}{\pi}}$
$P^T_{2q+1,q-1}$	$\mathcal{T}od(z)$	$\frac{2z}{(1-4z)^2}+\frac{z^2+z^3}{(1-4z)^3\sqrt{1-4z}}$	$q\ 2^{2q-1}+\frac{q(q-1)(q-2)}{120}\binom{2q}{q}+\frac{(q+1)q(q-1)}{120}\binom{2(q+1)}{q+1}$	$4^q\frac{8}{15}\ \sqrt{\frac{q^5}{\pi}}$
$P^T_{2q,q}$	$\mathcal{E}v(z)$	$\frac{4z-1+\sqrt{1-4z}}{2(1-4z)}$	$\binom{2q-1}{q}$	$4^q\ \sqrt{\frac{1}{4\pi q}}$
$P^T_{2q,q-1}$	$\mathcal{S}ev(z)$	$\frac{z}{1-4z}+\frac{z^2}{(1-4z)^2\sqrt{1-4z}}$	$4^{q-1}+\frac{2(2q-5)(2q-3)(2q-1)}{3(q-2)}\binom{2(q-3)}{q-3}$	$4^q\ \frac{1}{12}\ \sqrt{\frac{q^3}{\pi}}$

This allows us make the following conjecture about the asymptotical evaluation of the size of closed λ-terms:

Conjecture 1 *Let k_1 and k_0 be two constants. When q goes to ∞,*

$$T_{2q+1,0} \sim \frac{(2q+1)^{2q+1}}{\sqrt{q}}k_1 \qquad\qquad T_{2q,0} \sim \frac{(2q)^{2q}}{\sqrt{q}}k_0$$

[2]Like τ_{2q} and δ_{2q+1}, they correspond to non studied sequences according to the *On-Line Encyclopedia of Integer Sequences*.

Indeed one sees that for $2q+1$ and for $i = -1, 0, 1, ...$, the sequence of the last column is made of two sequences $\sqrt{q^{4i+1}}2^{2q+1}$ and $1/(2\sqrt{\pi}), 1/(4\sqrt{\pi}), 4/(15\sqrt{\pi}), ...$, that are multiplied element-wise. We notice that when i is q the sequence $\sqrt{q^{4i+1}}2^{2q+1}$ is $(2q+1)^{2q+1}/\sqrt{q}$. On another hand, we claim that when i goes to infinity (then q as well) the sequence $1/(2\sqrt{\pi}), 1/(4\sqrt{\pi}), 4/(15\sqrt{\pi}), ...$ tends to a limit k_1. Therefore $P^T_{n,0} = T_{n,0} \sim k_1(2q+1)^{2q+1}/\sqrt{q}$

Similarly, $P^T_{2q,q-i} \sim \sqrt{q^{4i-1}}4^q\, f(i)$ where $f(i)$ depends on i. We claim that $T_{2q,0} = P^T_{2q,0} \sim \sqrt{q^{4q-1}}4^q\, k_0 = k_0(2q)^{2q}/\sqrt{\pi}$ where $k_0 = \lim_{i\to\infty} f_0(i)$ (we claim again that this limit exists).

4 Normal forms

Lest us call $\mathcal{F}_m$ the set of normal forms with m de Bruijn indices and $\mathcal{G}_m$ the sets of normal forms with no head λ. The combinatorial structure equations are

$$\begin{aligned} \mathcal{G}_m &= \mathcal{I}(m) \uplus \mathcal{G}_m @ \mathcal{F}_m \\ \mathcal{F}_m &= \lambda\, \mathcal{F}_{m+1} \uplus \mathcal{G}_m \end{aligned}$$

Let $G_{n,m}$ be the number of normal forms of size n with no head λ and with de Bruijn indices in $\mathcal{I}(m)$ and $F_{n,m}$ be the number of normal forms of size n with de Bruijn indices in $\mathcal{I}(m)$. The relations between $G_{n,m}$ and $F_{n,m}$ are

$$\begin{aligned} G_{1,m} &= m \\ G_{n+1,m} &= \sum_{k=0}^{n} G_{n-k,m} F_{k,m} \end{aligned}$$

$$\begin{aligned} F_{1,m} &= m \quad = \quad G_{1,m} \\ F_{n+1,m} &= F_{n,m+1} + G_{n+1,m} \end{aligned}$$

whereas the relations between generating functions are

$$\begin{aligned} G_m(z) &= m\, z + z\, G_m(z)\, F_m(z) \\ F_m(z) &= z\, F_{m+1}(z) + G_m(z). \end{aligned}$$

The coefficients $F_{n,m}$ are given in Figure 3.

The functions $m \mapsto F_{n,m}$

Like for $m \mapsto T_{n,m}$, the functions $m \mapsto F_{n,m}$ are polynomials of degree $n+1 \div 2$, which we write P^{NF}_n and which are given in Figure 4. The coefficients of polynomials P^{NF}_n enjoy properties somewhat similar to those proved for polynomials P^T_n. In what follows we write $P_n(m)$ the polynomial $P^T_n(m)$, $Q_n(m)$ the polynomial associated with $G_{n,m}$, φ_n the leading coefficient of P_n, $\overline{\varphi_n}$ the leading

coefficient of Q_n, ψ_n the second leading coefficient of P_n and $\overline{\psi}_n$ the second leading coefficient of of Q_n. We have the equations

$$\begin{aligned} P_{n+1}(m) &= P_n(m+1) + Q_{n+1}(m) && (4)\\ Q_{n+1}(m) &= \sum_{k=0}^{n} Q_{n-k}(m) P_k(m) && (5) \end{aligned}$$

Proposition 7 *$deg(P^{NF}_{2p-1}) = deg(P^{NF}_{2p}) = p$.*

Proof: Admitted. □

We define eight generating functions:

$$\begin{aligned} \mathcal{F}ev(z) &= \sum_{i=0}^{\infty} \varphi_{2i} z^i & \overline{\mathcal{F}ev}(z) &= \sum_{i=0}^{\infty} \overline{\varphi}_{2i} z^i \\ \mathcal{F}od(z) &= \sum_{i=0}^{\infty} \varphi_{2i+1} z^i & \overline{\mathcal{F}od}(z) &= \sum_{i=0}^{\infty} \overline{\varphi}_{2i+1} z^i \\ \mathcal{SF}ev(z) &= \sum_{i=0}^{\infty} \psi_{2i} z^i & \overline{\mathcal{SF}ev}(z) &= \sum_{i=0}^{\infty} \overline{\psi}_{2i} z^i \\ \mathcal{SF}od(z) &= \sum_{i=0}^{\infty} \psi_{2i+1} z^i & \overline{\mathcal{SF}od}(z) &= \sum_{i=0}^{\infty} \overline{\psi}_{2i+1} z^i \end{aligned}$$

Proposition 8 *The leading coefficients of P^{NF}_{2q+1} are Catalan numbers.*

Proof: Admitted: $\mathcal{F}od(z) = \overline{\mathcal{F}od}(z) = C(z)$. □

Proposition 9 *The leading coefficients of the P^{NF}_n's for n even, are $P^{NF}_0 = 0$, $P^{NF}_2 = 1$ and $P^{NF}_{2q+4} = 2\binom{2q+1}{q}$, i.e., $P^{NF}_{2q+4} = 2P^{T}_{2q+2}$.*

Proof: From Equations 4 and 5,we get:

$$\begin{aligned} \varphi_{2(q+1)} &= \varphi_{2q+1} + \overline{\varphi}_{2(q+1)} \\ \overline{\varphi}_{2(q+1)} &= \sum_{i=0}^{q} \overline{\varphi}_{2q+1-2i} \varphi_{2i} + \sum_{i=0}^{q} \overline{\varphi}_{2q-2i} \varphi_{2i+1} \end{aligned}$$

Hence

$$\begin{aligned} \mathcal{F}ev(z) &= z\mathcal{F}od(z) + \overline{\mathcal{F}ev}(z) \\ \overline{\mathcal{F}ev}(z) &= z\overline{\mathcal{F}od}(z)\mathcal{F}ev(z) + z\overline{\mathcal{F}ev}(z)\mathcal{F}od(z) \end{aligned}$$

from which we get

$$\overline{\mathcal{F}ev}(z) = \frac{z\mathcal{F}od(z)\mathcal{F}ev(z)}{1 - z\mathcal{F}od(z)} \qquad (6)$$

then

$$\mathcal{F}ev(z) \;=\; z\mathcal{F}od(z) + \frac{z\mathcal{F}od(z)\mathcal{F}ev(z)}{1 - z\mathcal{F}od(z)}$$

and

$$\mathcal{F}ev(z) - z\,\mathcal{F}od(z)\mathcal{F}ev(z) \;=\; z\,\mathcal{F}od(z) - z^2\mathcal{F}od(z)^2 + z\,\mathcal{F}od(z)\mathcal{F}ev(z)$$

and

$$\begin{aligned}
\mathcal{F}ev(z) &= \frac{z\mathcal{F}od(z) - z^2\mathcal{F}od(z)^2}{1 - 2z\mathcal{F}od(z)} \\
&= \frac{z}{\sqrt{1-4z}} \;=\; \frac{z\sqrt{1-4z}}{1-4z} \\
&= \frac{z}{1 - 2zC(z)}.
\end{aligned}$$

Hence $\mathcal{F}ev(z)$ is the generating function of the sequence $\varphi_0 = 0$, $\varphi_2 = 1$ and $\varphi_{2q+4} = 2\binom{2q+1}{q}$. □

Corollary 1 $\overline{\mathcal{F}ev}(z) = \frac{4z-1+(1-2z)\sqrt{1-4z}}{2\sqrt{1-4z}}$

Proof: From Equation 6

$$\begin{aligned}
\overline{\mathcal{F}ev}(z) &= zC(z)^2\mathcal{F}ev(z) \\
&= \frac{(1-\sqrt{1-4z})^2\sqrt{1-4z}}{4z(1-4z)} = \frac{4z-1+(1-2z)\sqrt{1-4z}}{2(1-4z)} \\
&= \frac{z}{\sqrt{1-4z}} - \frac{1-\sqrt{1-4z}}{2} = z^2C'(z).
\end{aligned}$$

□

Proposition 10 *The second leading coefficients of the P^{NF}_{2q+1}'s are $\psi_0 = 0$, $\psi_3 = 1$ and $\psi_{2q+5} = (q+3)\binom{2q+1}{q}$.*

Proof: From the proof of Proposition 7,

$$\begin{aligned}
\psi_{2q+1} &= \varphi_{2q} + \overline{\psi}_{2q+1} \\
\overline{\psi}_1 &= 0 \\
\overline{\psi}_{2q+3} &= \sum_{i=0}^{q+1} \overline{\varphi}_{2i}\varphi_{2q-2i} + \sum_{i=0}^{q} \overline{\psi}_{2i+1}\varphi_{2q-2i+1} + \sum_{i=0}^{q} \psi_{2i+1}\overline{\varphi}_{2q-2i+1},
\end{aligned}$$

from which we get

$$\begin{aligned}
\mathcal{S}\mathcal{F}od(z) &= \mathcal{F}ev(z) + \overline{\mathcal{S}\mathcal{F}od}(z) \\
\overline{\mathcal{S}\mathcal{F}od}(z) &= \overline{\mathcal{F}ev}(z)\mathcal{F}ev(z) + z\,\overline{\mathcal{S}\mathcal{F}od}(z)\mathcal{F}od(z) + z\,\mathcal{S}\mathcal{F}od(z)\overline{\mathcal{F}od}(z).
\end{aligned}$$

Then we get

$$\overline{\mathcal{SF}od}(z)(1-z\mathcal{F}od(z)) \quad = \quad \mathcal{F}ev(z)\overline{\mathcal{F}ev}(z) + z\mathcal{SF}od(z)\overline{\mathcal{F}od}(z).$$

We know that $1 - z\mathcal{F}od(z) = 1 - zC(z) = 1/C(z)$, then

$$\overline{\mathcal{SF}od}(z) \quad = \quad \frac{z}{\sqrt{1-4z}}\; z^2C'(z)C(z) + z\,\mathcal{SF}od(z)C(z)^2$$

and

$$\mathcal{SF}od(z) \quad = \quad \mathcal{F}ev(z) + \frac{z^3\,C(z)C'(z)}{\sqrt{1-4z}} + z\mathcal{SF}od(z)C(z)^2.$$

We know $1 - z\,C(z)^2 = C(z)\sqrt{1-4z}$, then

$$\begin{aligned}
\mathcal{SF}od(z) &= \left(\frac{z}{\sqrt{1-4z}} + \frac{z^3C(z)C'(z)}{\sqrt{1-4z}}\right)\frac{1}{C(z)\sqrt{1-4z}} \\
&= \frac{z}{C(z)\,(1-4z)} + \frac{z^3\,C'(z)}{1-4z} \\
&= \frac{z^2}{(1-4z)\sqrt{1-4z}} + \frac{z}{\sqrt{1-4z}}.
\end{aligned}$$

which is the generating function of the sequence $0, 1$ followed by $(q+3)\binom{2q+1}{q}$. □

Recall the generating functions we have computed:

$$\begin{aligned}
\mathcal{F}od(z) &= \frac{1-\sqrt{1-4z}}{2z} \\
\mathcal{F}ev(z) &= \frac{z}{\sqrt{1-4z}} \\
\mathcal{SF}od(z) &= \frac{z^2}{(1-4z)\sqrt{1-4z}} + \frac{z}{\sqrt{1-4z}}.
\end{aligned}$$

5 Generating functions for terms

We consider the bivariate generating function for terms which coefficients are the $T_{n,m}$ and the vertical generating functions which gives the $T_{n,m}$ for each value of m.

The bivariate generating function for terms

Let $T(z,u)$ be the bivariate generating function of $T_{n,m}$.

$$T(0,u) \quad = \quad 0$$

and

$$\begin{aligned} T(z,u) &= \sum_{n,m\geq 0} T_{n,m} z^n u^m \\ &= z \sum_{m\geq 0} m u^m + \sum_{n\geq 1\, m\geq 0} T_{n-1,m+1} z^n u^m + z T^2(z,u) \\ &= \frac{z\,u}{(1-u)^2} + \sum_{n\geq 0\, m\geq 1} T_{n,m} z^{n+1} u^{m-1} + z T^2(z,u) \\ &= \frac{z\,u}{(1-u)^2} + \frac{z}{u}(T(z,u) - T(z,0)) + z T^2(z,u) \end{aligned}$$

Hence

$$z u T^2(z,u) + (z-u) T(z,u) + \frac{z\,u^2}{(1-u)^2} - z T(z,0) = 0$$

and

$$\boxed{T(z,u) = \frac{-(z-u)+\sqrt{(z-u)^2+4zu\left(\frac{z\,u^2}{(1-u)^2}-zT(z,0)\right)}}{2zu}.}$$

We notice that

$$\lim_{u\to 0} T(z,u) = T(z,0).$$

On the other hand we see the presence of $T(z,0)$ in the lefthand side, which shows that the equation is not a definition of T but rather an equation which characterizes T as a fixed point. Presented like that, the equation is not amenable to the same treatment as those presented in Flajolet and Sedgewick [8] and specialists consider it as difficult and no result is known about the asymptotic behavior of its coefficient.

Vertical generating functions

We see that

$$T_{n,m+1} = T_{n+1,m} - \sum_{k=0}^{n} T_{n-k,m} T_{k,m}.$$

Hence

$$T^{\langle m\rangle}(0) = 0$$

and

$$\begin{aligned} T^{\langle m+1\rangle}(z) &= \sum_{n=0}^{\infty} T_{n,m+1} z^n \\ &= \sum_{n=0}^{\infty} T_{n+1,m} z^n - \sum_{n=0}^{\infty} \sum_{k=0}^{n} T_{n-k,m} T_{k,m} z^n \\ &= \frac{T^{\langle m\rangle}(z)}{z} - (T^{\langle m\rangle}(z))^2 \end{aligned}$$

In other words

$$z(T^{\langle m\rangle}(z))^2 - T^{\langle m\rangle}(z) + zT^{\langle m+1\rangle}(z) = 0.$$

Hence

$$T^{\langle m\rangle}(z) = \frac{1 - \sqrt{1 - 4z^2T^{\langle m+1\rangle}(z)}}{2z}.$$

We see that $T^{\langle m\rangle}$ is defined from $T^{\langle m+1\rangle}$. Like the bivariate generating function $T(z, u)$, $T^{\langle m\rangle}(z)$ is also difficult to study, because we have $T^{\langle m\rangle}$ defined in term of $T^{\langle m+1\rangle}$.

6 Conclusion

We have given several parameters on numbers of untyped lambda terms and untyped normal forms and proved or conjectured facts about them. On another direction, it could be worth to study typed lambda terms, whereas we have only analyzed untyped lambda terms in this paper.
